

(a) Split proxy W into blocks; hold some out

held out

$2^5 - 2 = 30$ splits in all

(b) Learn Z from X and the kept blocks

$W_2, \dots, W_5$ and X

pick ϕ to minimize

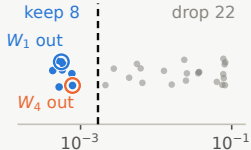

$\tilde{D}_S^2$

Z

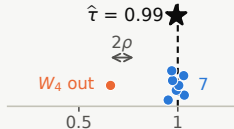

never sees the held-out blocks

(c) Given Z , do the held-out blocks predict A ?

screen statistic; keep below t

(d) Repeat; the largest component gives $\hat{\tau}$

one dot per split; dashed τ
